Antegrade Continence Enema (ACE) Procedure

What Is ACE?

The ACE procedure was developed to treat fecal incontinence (soiling) and severe constipation. The doctor uses a piece of bowel tissue to create a passageway between the large intestine and an opening in the lower abdomen or belly button.

A catheter is placed into the passageway once a day to give an enema. This flushes out the stool through the rectum and into the toilet. It usually takes 30-45 minutes to pass the stool and empty the entire colon. This prevents constipation and — because the colon is clean — soiling.

Indications

At Gillette, this operation is performed most often on patients who have spina bifida or spinal-cord injuries, conditions that prevent good bladder and bowel control. People who have these conditions may experience severe constipation or fecal incontinence (soiling).

Good Candidates

Success following an ACE procedure depends greatly on careful patient selection. Good candidates for the ACE procedure are physically capable and emotionally ready to handle a strict routine of intermittent enemas. Or, their caregivers are motivated to follow the routine.
What to Expect

**Before Surgery:** You'll need to do a day or two of home bowel preparation to clean your bowel.

**During Surgery:** The surgery can last many hours if more than one procedure is done.

**After Surgery:** You'll have an IV to give you medicine, fluids and nutrition. When bowel activity resumes, you'll slowly advance from clear liquids to full liquids to soft foods.

There will be a dressing or covering over your incision. There will be a catheter in your new ACE site that will remain capped until your doctor tells you to begin using it.

**After Recovery:** When you return to the clinic, about three weeks after surgery, your doctor and nurse will teach you how to use your new ACE. If you are completely healed, you’ll go home with a regular schedule for catheterizing your new ACE.
